This report covers 88 pages.

## 1 Introduction

The PA0 sodar is a sodar system (sodar=sound detection and ranging) for wind measurements in the lower atmosphere. The device provided by the French company Remtech, designed with consideration for the needs of the wind energy industry. This report describes a test of the accuracy of the RSD (Remote Sensing Device) with the serial number 239 against conventional wind measurements with mast mounted cup anemometers and conventional wind vanes.

The calibration describes the accuracy of the measurements of the RSD for the environmental conditions present at the test site during the test period. The environmental conditions present at an application of the RSD may deviate from the conditions present at the Calibration Test.

The reported Calibration Test follows the latest requirements as developed in the frame of the ongoing revision of the standard IEC 61400-12-1 [2]. The test took place at a special test station for remote wind sensing devices in Eastern Friesland, where a 135 m high met mast is available.

Before the official test period no preliminary intercomparison between RSD and reference has been done. The valid data of the RSD that were measured during calibration were not filtered.

This report covers 88 pages.

## 2 Measurement Site and Met Mast

The measurement is located near the village Georgsfeld, approximately 5 km north-west of Aurich, in the region Eastern Frisia, which is in the north west of the German state of Lower Saxony. The distance to the North Sea is approximately 20 km.

The area around the met mast position is characterised by flat terrain. The terrain height at the met mast location is about 6 m above sea level. The best fit of a plane to the terrain up to 5km distance going through the bottom of the mast has no significant slope. The maximum deviation of the terrain to this plane is 11 m.

The landscape is characterised by farmland with closed appearance. The land development in the environment mainly consists of small villages, with tree rows along roads and field borders. Noteworthy are the town of Aurich (40 000 inhabitants) 5 km to the South East and a forest 1 km to the North West. In a distance 70 m to the mast an earth dike with low trees runs from South West to North East.

A map of the measurement site is given Figure 2.1. Photos of the met mast and a panoramic view of the site are shown in Figure 2.2 and Figure 2.3.

Figure 2.1: Map of the measurement site. The wind turbines E-126 limit the measurement sector. The met mast is marked by a black square with the black dots marking the anchor points of the guy wires. The RSD was located on the field northwest of the met mast (circle).

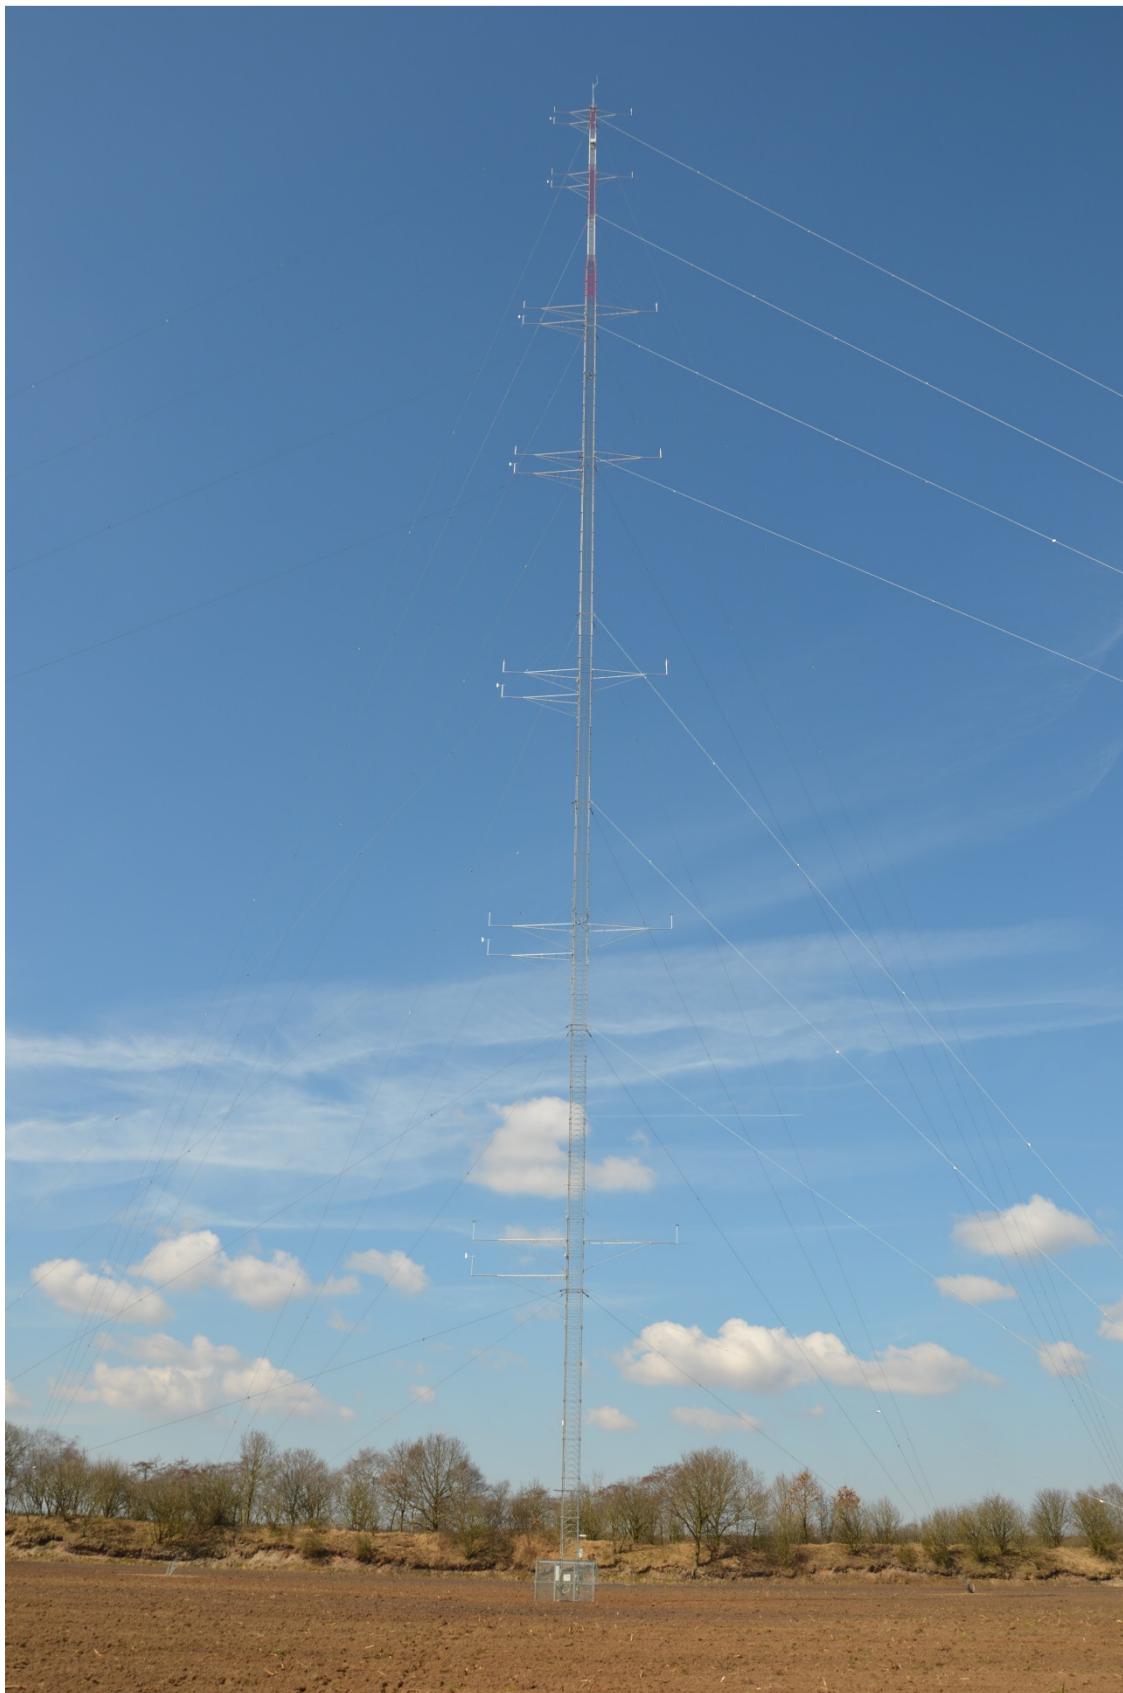

Figure 2.2: Photo of the 130 m high met mast near Georgsfeld, looking in direction southwest.

Figure 2.3: Panoramic view of the measurement site taken 13 m from the bottom of the met mast (continued).

S=180°

W=270°

N=360°

Figure 2.3: Panoramic view of the measurement site taken 13 m from the bottom of the met mast (end).

During the measurement, the RSD was installed 138.5 m west of the met mast (Figure 2.4).

The met mast is positioned about 357 m west of a test wind turbine. The test wind turbine and other neighbouring turbines influence the airflow at the mast at easterly and south westerly wind directions. The coordinates and the resulting wake effects calculated according IEC 61400-12-1 for power performance measurements [1] can be seen in detail in Table 2.1. From all these wakes, an undisturbed and applicable sector of 253° to 29° remains for testing the RSD. The measurement sector must be reduced further for some reference sensors due to mast effects (see Table 2.2). The RSD was aligned to 83°. The bearing was taken over an edge of the frame of the RSD.

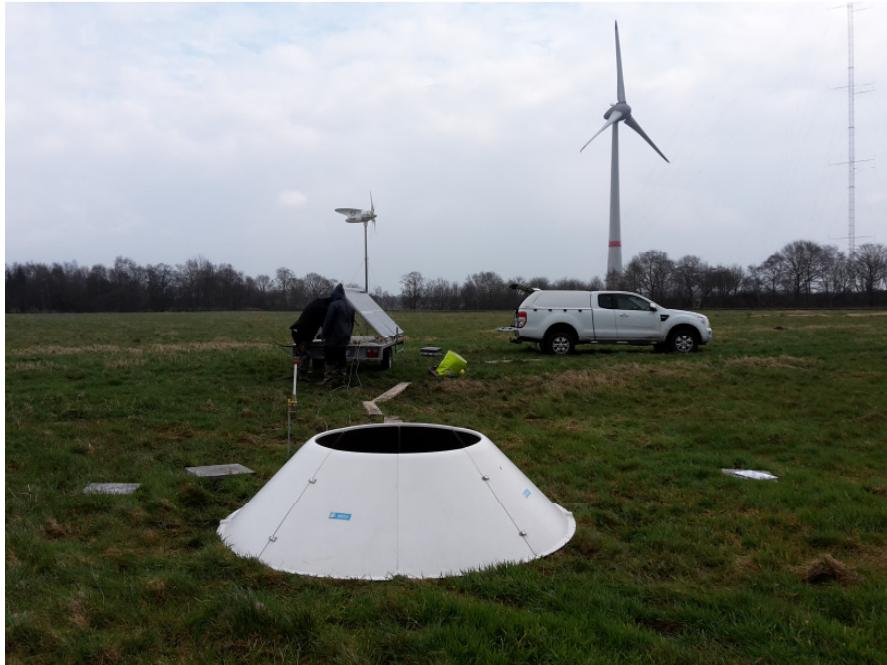

Figure 2.4: The RSD under test installed next to the met tower.

The met mast is equipped with several cup and ultrasonic anemometers as well as wind vanes in different heights above ground. The airflow at the positions of the anemometers and vanes is significantly influenced by flow disturbance caused by the mast and neighbouring sensors (blockage effects, flow acceleration effects). The least influence occurs at the cup anemometer of type Thies First Class Advanced which is mounted at 135 m height above ground at the top of the met mast. An individual wind direction depending correction has been applied to the wind speed measurements of the cup and ultrasonic anemometers which are mounted on side booms to the mast (all mounting heights except 135 m). Those correction functions have been determined empirically. The cup anemometers are of class 0.9A according to reference [1], [3]. The cup and also the ultrasonic anemometers have been calibrated in a wind tunnel according to DKD and MEASNET [4]. One of the calibration wind tunnels of DWG is applied by the German authority for controlling units, Physikalisch-Technische Bundesanstalt (PTB), for defining the unit m/s in airflow measurements. A more accurate tracing back of the anemometer measurements is currently not possible. The ultrasonic anemometers were calibrated for different horizontal and vertical orientations. The wind measurements with the mast follow the requirements of IEC 61400-12-1 [1].

A list of the undertaken comparisons of sensors of the met mast and measurements of the RSD are given in Table 2.2. From the table, the disturbed sectors caused by the mast and the neighbouring turbines and the chosen evaluation sectors can be seen. The positions of the laser beams in dependence of the measuring height have been taken into account for the calculation of the disturbed sectors. Table 2.3 shows the specifications of the sensors mounted at the met mast.

Object	Position		Rotor diameter D	Distance from met mast	Direction from met mast	Met Mast in Wake	
	X	Y				from	to

### 3 Set-Up of the RSD, Data Collection and Data Processing

#### 3.1 Set-Up of the RSD

The evaluated measurement period was from 2016-05-04 to 2016-07-21. The RSD was supplied by solar panels and a small wind turbine (which was not activated) in the measurement period. The basic information and key settings of the RSD are shown in the following table. The settings have not been changed in the measurement period.

Evaluated measurement period	2016-05-04 to 2016-07-21
RSD model	PA0 SC
Unit serial number	239
Beam angle from vertical	25°
Selected measurement heights	40 m, 60 m, 80 m, 100 m, 120 m, 140 m
North orientation during test	83°
Power supply	Solar
Firmware	V9.06.3

Table 3.1 Basic information and key settings of the tested RSD

The vertical and horizontal alignment of the RSD was adjusted by staff member of DWG at the start of the measurement. The horizontality was adjusted with the use of a water level. The horizontal orientation was controlled by a compass over the outer edge of the sodar. The horizontal orientation was 83°. The alignment did not change during the course of the measurements.

The RSD and the data acquisition system of the met mast have been synchronised to UTC time at the beginning of the campaign. During the measurement period, the time was synchronised by GPS.

#### 3.2 Data Collection

The RSD stores data files in ASCII/text format converted into columns instead of data blocks thanks to the conversion software SodarWinPro provided by Remtech.

#### 3.3 Data Processing

##### 3.3.1 Extrapolation of Horizontal Wind Speed Component and its Standard Deviation as Measured by Anemometer

The RSD allows measurement height selection in integer meter values user's selectable steps. During this experiment 20 m layers was chosen. To evaluate the horizontal wind speed of same height levels the wind speeds of cup anemometers have been interpolated.

For this, a power law has been adjusted to the measurements of the horizontal wind speed component of cup anemometer for adjacent sensors (e.g. 135 m and 120.4 m) measurement height within each 10-minute period:

$$\alpha_v = \frac{\ln\left(\frac{v_{Anemometer,h_1}}{v_{Anemometer,h_2}}\right)}{\ln\left(\frac{h_1}{h_2}\right)} \quad (1)$$

$$v_{Anemometer,interpolated} = v_{Anemometer,h_1} \left( \frac{h_{interpolation}}{h_1} \right)^{\alpha_v}$$

where

- $\alpha_v$ : power law exponent in terms of the horizontal wind speed component
- $h_1$ : measurement height of anemometer below height of reference
- $h_2$ : measurement height of anemometer above height of reference
- $h_{interpolation}$ : interpolation height
- $v_{Anemometer,h_1}$ : measurement of horizontal wind speed component of anemometer at height  $h_1$
- $v_{Anemometer,h_2}$ : measurement of horizontal wind speed component of anemometer at height  $h_2$
- $v_{Anemometer,interpolated}$ : interpolated wind speed

### 3.3.2 Correction of Wind Speeds Measured by Boom Mounted Anemometers

The anemometers on the mast mounted below the mast top are influenced by the flow blockage effects and flow acceleration effects caused by the mast. These mast effects on the anemometer measurements have been corrected by empirically determined corrections.

### 3.3.3 Wind Shear

A power law has been adjusted to the measurements of the horizontal wind speed component of the RSD at two measurement heights as close to a pair of successive measurement heights at the met mast within each 10- minute period (see eq. (1)). The wind shear exponents determined from the measurements of the RSD have been compared to the wind shear exponents determined from the mast measurements.

### 3.3.4 Wind Direction

The wind directions measured by the RSD as average of 10-minute periods have been compared directly to the measurements with the vanes at the nearest measurement heights of the mast. Small deviations in the measurement heights of the RSD and the heights of the reference sensors on the mast have been ignored.

### 3.4 Data Filtering

The following data filtering has been applied for the comparison of the measurements of the RSD and the mast based sensors:

- No filtering has been applied for the RSD data which was making itself the decision for valid data (invalid data were quoted with -9999).
- Only wind directions, where the RSD and the reference sensor are exposed to free wind conditions (no wake effects), have been considered, i.e. the measurement sector according to Table 2.2 has been applied.
- Only wind speeds above 4 m/s as measured by the reference anemometer have been considered for the following reasons:
  - The wind tunnel calibration of the cup anemometer has been performed in the wind speed range 4-16 m/s according to MEASNET [4]. Despite the limitation of the wind tunnel calibrations to 16 m/s, the wind speed was not limited for testing the RSD in order to gain indications for the accuracy at higher wind speeds.
  - At low wind speeds, the cup anemometer measurements are linked to higher uncertainties.
  - Lower wind speeds are less relevant as hardly any energy is produced by wind turbines below 4 m/s.

It is noted that the derived results are valid only for these filters. Thus, the evaluated accuracy of the RSD can be expected in a later application only if the above flag filter of the RSD is applied.

## 4 Results of Calibration Test

### 4.1 Accuracy of the RSD in Terms of Availability

A total amount of 10534 10-minute periods was covered by the evaluated measurement period.

For availability evaluation the RSD has been considered as measurement without met mast. That means no wind directions or wind speed filters have been applied. The so evaluated data availability at the different measurement heights is shown in Figure 4.1. During the test the RSD operated without malfunction.

As can be seen in Figure 4.1, the availability of horizontal wind speed has values of up to about 80% for measurement heights between 40 m and 100 m. Over 100 m the data availability decreases with increasing measurement height.

The data availability depends on weather during test, because during too heavy rain the sodar writes “-9999” for values of horizontal wind speed.

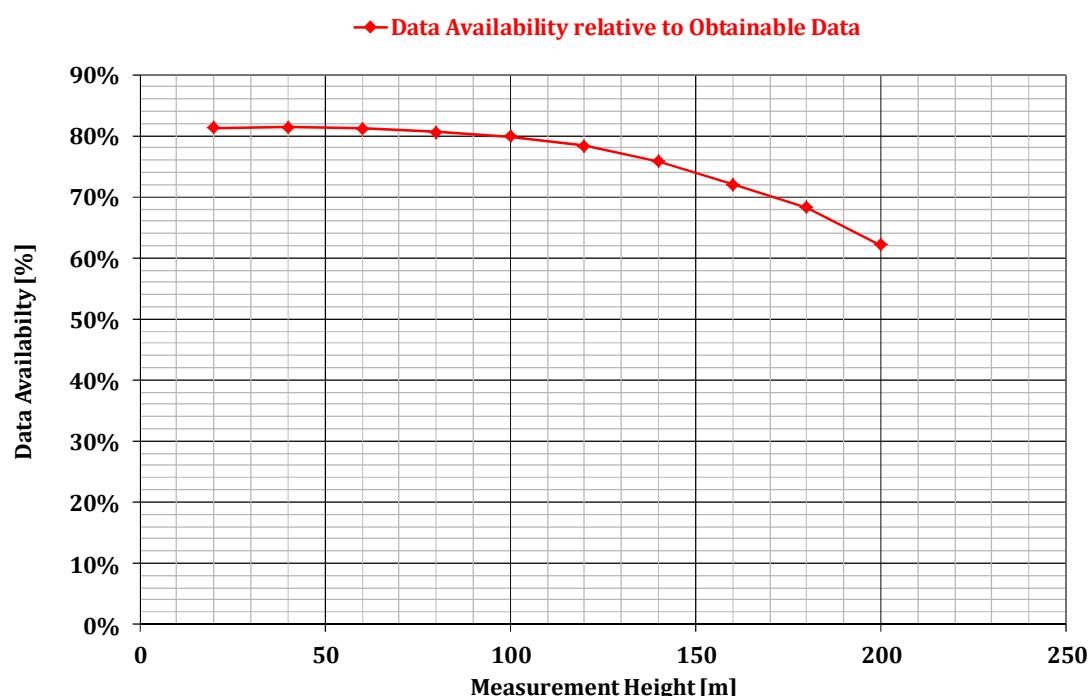

Figure 4.1 Availability of measurement of the horizontal wind speed component at different heights as measured by RSD.

## 4.2 Accuracy in Terms of the Horizontal Wind Speed Component

Detailed results of the comparison of cup anemometer measurement and measurement of the RSD in terms of the horizontal wind speed component are presented in the following sub chapters. The results can be summarised as follows:

- For the measurement heights between 140 m to 80 m the 10-minute mean values of the horizontal wind speed component as measured by the RSD and by cup anemometers show a good correlation (square of correlation coefficient about 0.95 to 0.96). Due to site effects the correlation decreases for lower measurement heights (for 60 m to about 0.94 and for 40 m to 0.89).
- For measurements height between 140 m and 60 m the horizontal wind speed component of the RSD is slightly overestimated with about 1.7% or 0.1m/s.
- For measurements height between 140 m and 60 m the horizontal wind speed component of the RSD show values of standard deviation of deviation of about slightly above 6%.
- The scatter plots of horizontal wind speed components show a good accuracy with a pleasurable precision.

As the statistics gained from the 10-minute data can in principle be influenced by the distribution of data within the measurement period, the measurements of the RSD have been bin averaged against the cup anemometer measurements, and the bin wise deviation between the measurements has been analysed. For measurement heights between 140 m to 100 m the bin wise deviation of horizontal wind speed between met mast and RSD is higher than the uncertainty of the cup anemometer measurements for bins between 4 m/s - 7 m/s (Figure 4.4, Figure 4.6, Figure 4.8). For wind speeds between 7 m/s – 14 m/s the bin wise deviation is in the main smaller than uncertainty of anemometer. The tendency for overestimating the horizontal wind speed component decreases with decreasing measurement height (Figure 4.2). For 80 m and 60 m the horizontal wind speed component is mostly lower than uncertainty of anemometer measurement (Figure 4.8, Figure 4.10).

As the measurements with the cup anemometers are traced back to national standards, the comparison between the cup anemometers and the RSD can be used in order to define an uncertainty of the wind speed measurement of the RSD. The following uncertainty components have been considered in order to evaluate the uncertainty of the measurements of the RSD:

- Wind tunnel calibration of the cup anemometers
- Classification of the cup anemometers according to IEC 61400-12-1
- Cup anemometer mounting effects
- Uncertainty of correction of mast effects on anemometers
- Bin wise deviation of RSD and cup anemometer measurements
- Statistical uncertainty of bin average of deviation of RSD and cup anemometer measurements

The different uncertainty components have been treated as independent uncertainties for the evaluation of the total uncertainty of the measurements of the RSD as gained from the comparison.

Total results like shown in right column of Table 4.1, etc. are given in expanded uncertainty. The expanded uncertainty assigned to the measurement results is obtained by

multiplying standard uncertainty by the coverage factor  $k=2$ . It has been determined in accordance with DAkkS-DKD-3. The value of the measurand lies within the assigned range of values with a probability of 95%. To get the single uncertainty ( $k=1$ ) with confidence of 68%, the expanded uncertainty has to be divided by two.

The resulting wind speed dependent uncertainties of the measurements of the horizontal wind speed component by the RSD are in the order of about 3-6% (expanded uncertainty  $k=2$ ) in most wind speed bins for all measurement heights. The variation of the uncertainty reaches from 2.7% to 18% for the different measurement heights and wind speed bins (Table 4.1 to Table 4.6)

It is noted that the uncertainty of the RSD as resulting from this comparison does not reflect all uncertainties of the system during an application at another site. The following additional uncertainties should be considered for an application of the system:

- The RSD measurements are influenced by environmental conditions, like e.g. wind shear. Thus, there is an additional uncertainty due to different environmental conditions during the calibration and during the application of the RSD.
- Mounting errors of the RSD during an application (vertical alignment)

Detailed ambient conditions dependent on wind speed and wind direction which were present during the test can be seen in Appendix A.

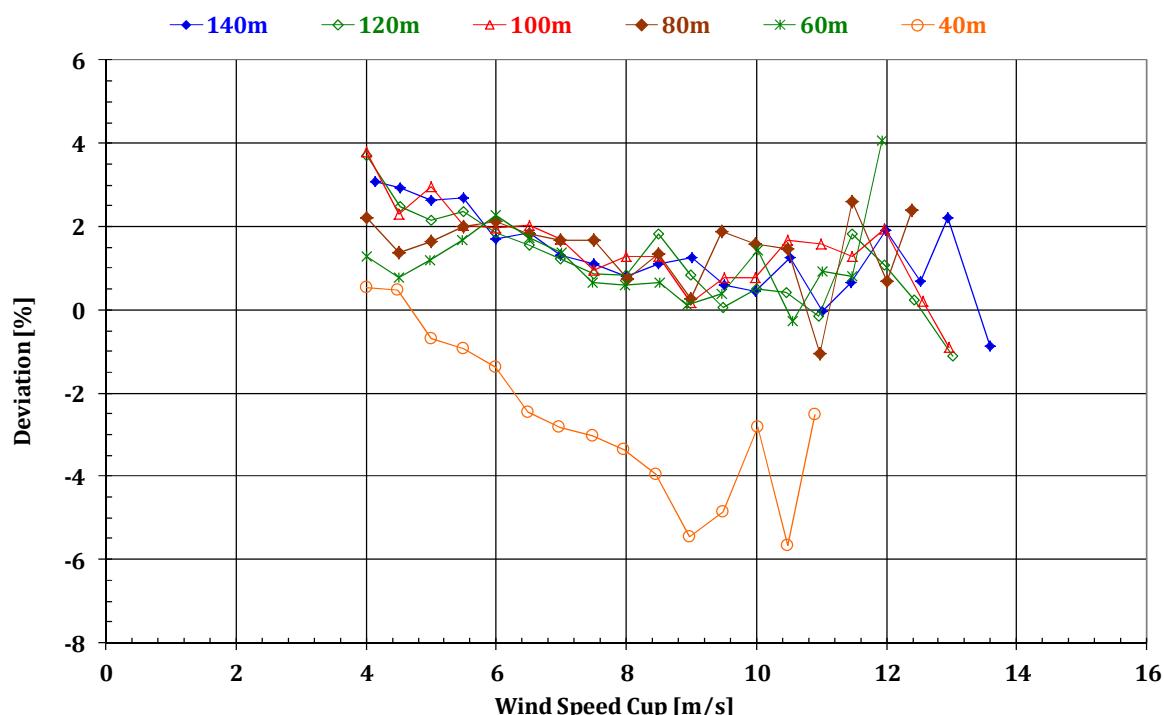

Figure 4.2 Overview of bin averaged deviations of 10-minute averages of the horizontal wind speed component measured by RSD against cup anemometer measurements at several heights. A positive sign of the shown deviation represents higher values measured by RSD.

#### 4.2.1 Accuracy of RSD in Terms of 10-Minute Averages of the Horizontal Wind Speed Component at 140 m Measurement Height

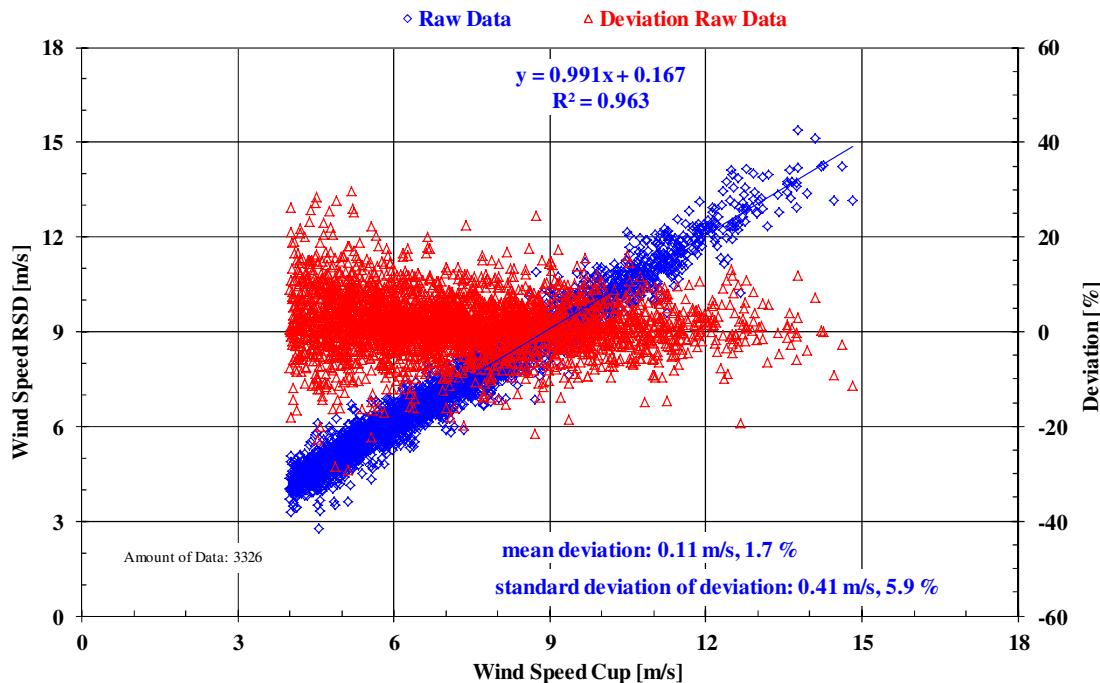

Figure 4.3 Scatter plot of horizontal wind speed component as measured by RSD against cup anemometer readings at 140 m height above ground and the deviation between both values in percent of the wind speed. Each point represents a 10-minute average.

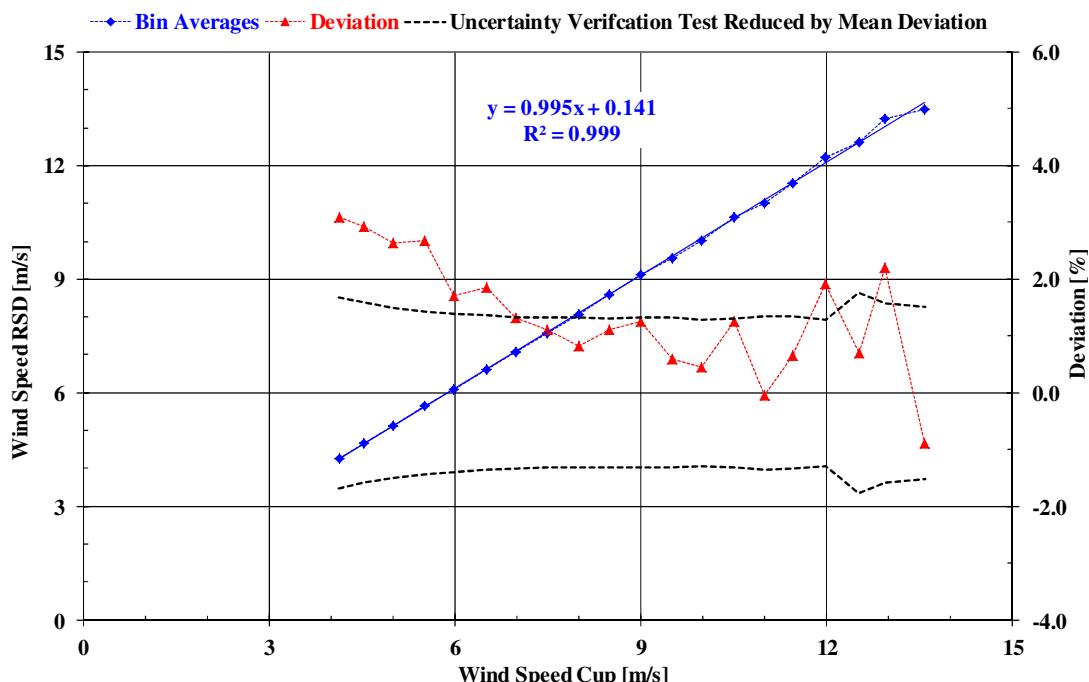

Figure 4.4: Bin analysis of 10-minute averages of the horizontal wind speed component measured by RSD against cup anemometer measurements at 140 m height above ground. A positive sign of the shown deviation represents higher values measured by RSD.

Table 4.6 Bin analysis of 10-minute averages of the horizontal wind speed component measured by RSD against cup anemometer measurements at 40 m height above ground. A positive sign of the shown deviation represents higher values measured by RSD. The right column shows the total expanded uncertainty (k=2) of the RSD as derived from the test.

### 4.3 Accuracy of the RSD in Terms of Wind Shear

Wind shear exponents have been calculated for each 10-minute period from the measurements of the RSD and the measurements of the met mast at nearly same measurement heights as explained in chapter 3.3.3.

Detailed results of the comparison of shear exponents are presented in the following sub chapters.

The following conclusions can be drawn:

- The comparison of the shear exponents derived from the measurements of the RSD and the cup anemometer measurements for each 10-minute period shows poor correlation (Figure 4.15, Figure 4.17, Figure 4.19, Figure 4.21, Figure 4.23 and Figure 4.25). The square of the correlation coefficient is about 0.37 to 0.6 in the different height ranges.
- The bin-averaged wind shear exponents derived from the measurements of the RSD and the cup anemometer measurements show a moderate to good correlation with a squared correlation coefficient of about 0.91 – 0.97 for measurement height between 40m and 135m.
- The standard deviation of deviation of the mean shear exponents gained by RSD slightly increase with increasing measurement height from 0.133 to 0.214.

In all height levels, the bin averaged difference in wind shear exponent between cup anemometers and RSD shows strong wind shear dependence. The RSD overestimates wind shear at low shear exponents and underestimates at high wind shears. The shear exponents where overestimation changes to underestimation is at all heights about 0.2 to 0.4.

The comparison of the shear exponents measured by the cup anemometers and by the RSD can be used in order to define an uncertainty of the measurement of the wind shear of the RSD. The following components have been considered in order to evaluate this uncertainty:

- Wind tunnel calibration of cup anemometers
- Classification of the cup anemometers according to IEC 61400-12-1
- Cup anemometer mounting effects
- Uncertainty of correction of mast effects on anemometers
- Bin wise deviation of RSD and cup anemometer measurements in terms of the wind shear
- Statistical uncertainty of bin average of deviation of RSD and cup anemometer measurements in terms of the wind shear

The respective uncertainties of the two cup anemometer measurements applied to evaluate the reference wind shear have been cumulated under careful and conservative consideration of the correlation of the uncertainties between the cup anemometers. The uncertainty components listed above have then been treated as independent uncertainties for the evaluation of the total uncertainty of the wind shear measurement by the RSD as gained from the comparison.

The resulting standard uncertainty of the RSD measurements in terms of the wind shear exponents is below 0.1 ( $k=2$ ) for a shear range of 0.1 to 0.4 in all height ranges with the exception of wind shear between 40 and 60 m and between 140 m and 120 m. This is considered as good. For negative wind shear and high wind shear above 0.5 uncertainty

increases significantly to values of 0.3 and more. This is considered unfavourably for sites with such wind shear conditions.

#### 4.3.1 Accuracy of RSD in Terms of Wind Shear between 140 m and 120 m

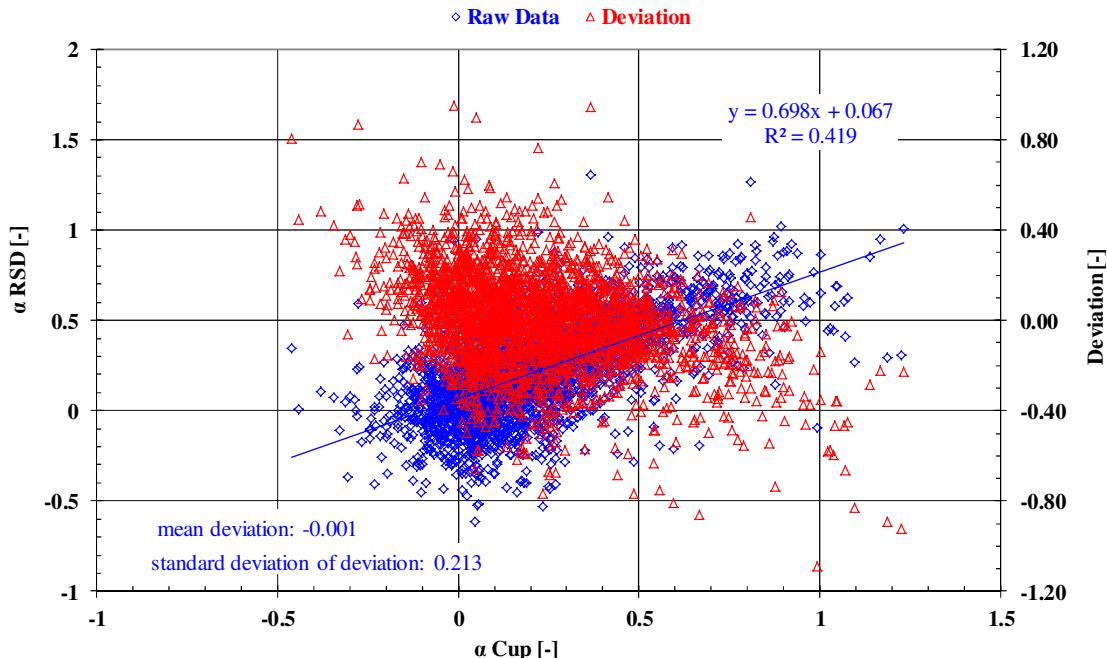

Figure 4.15: Scatter plot of shear exponents as measured by RSD between 140 m and 120 m height against cup anemometer measurements between 135 m and 120.3 m height and the deviation between both shear exponents. Each point represents a 10-minute period.

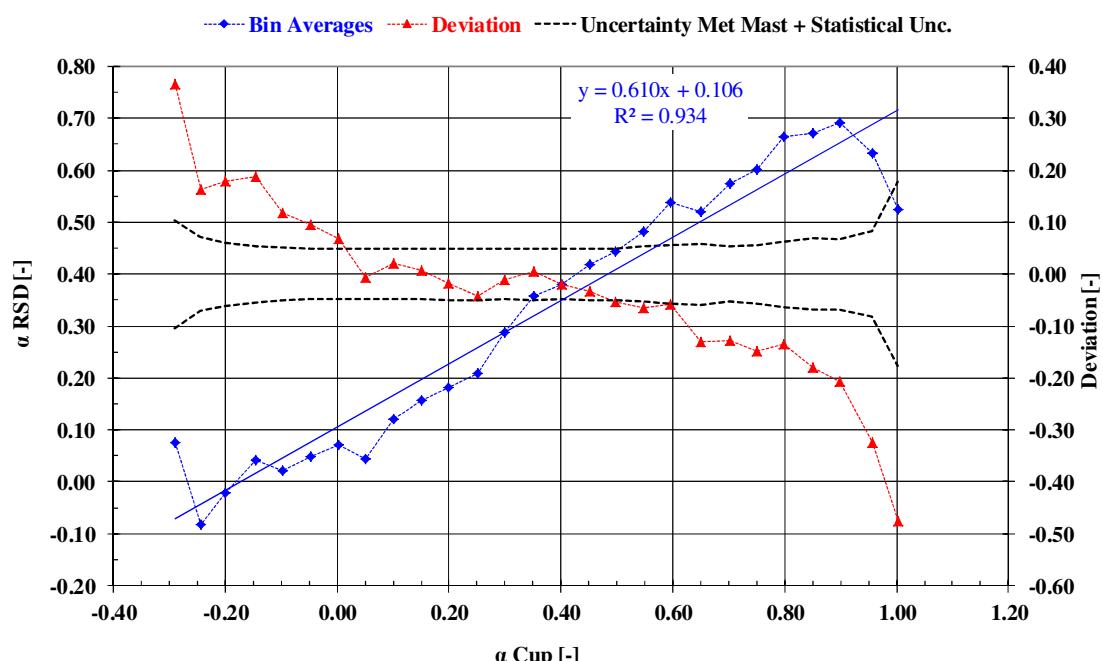

Figure 4.16: Bin analysis of shear exponents measured by RSD between 140 m and 120 m against cup anemometer measurements between 135 m and 120.3 m height above ground. A positive sign of the shown deviation represents higher values measured by RSD.

Table 4.12: Bin analysis of shear exponents measured by RSD between 60 m and 40 m against cup anemometer measurements between 60.4 m and 40.3 m height above ground. A positive sign of the shown deviation represents higher values measured by RSD. The right column shows the total expanded uncertainty (k=2) of the RSD as derived from the test.

#### 4.4 Accuracy of the RSD in Terms of Wind Direction

The wind direction as measured by the RSD and by the met mast is compared for measurement heights of 140 m, 120 m, 100 m, 80 m, 60 m, 40 m in the following sub chapter. The following conclusions can be drawn:

- The wind direction as measured by the RSD and by the vane correlates good with squared correlation coefficient of 0.998 – 0.999. Hardly any outlier data is observed in the respective scatter plot, see Figure 4.27, Figure 4.29, Figure 4.31, Figure 4.33, Figure 4.35 and Figure 4.37.
- The RSD shows value of mean deviation of -2.60° to 0.42°.
- Overall, the wind direction measurement of the RSD is considered as good.

##### 4.4.1 Wind Direction at 140 m Height

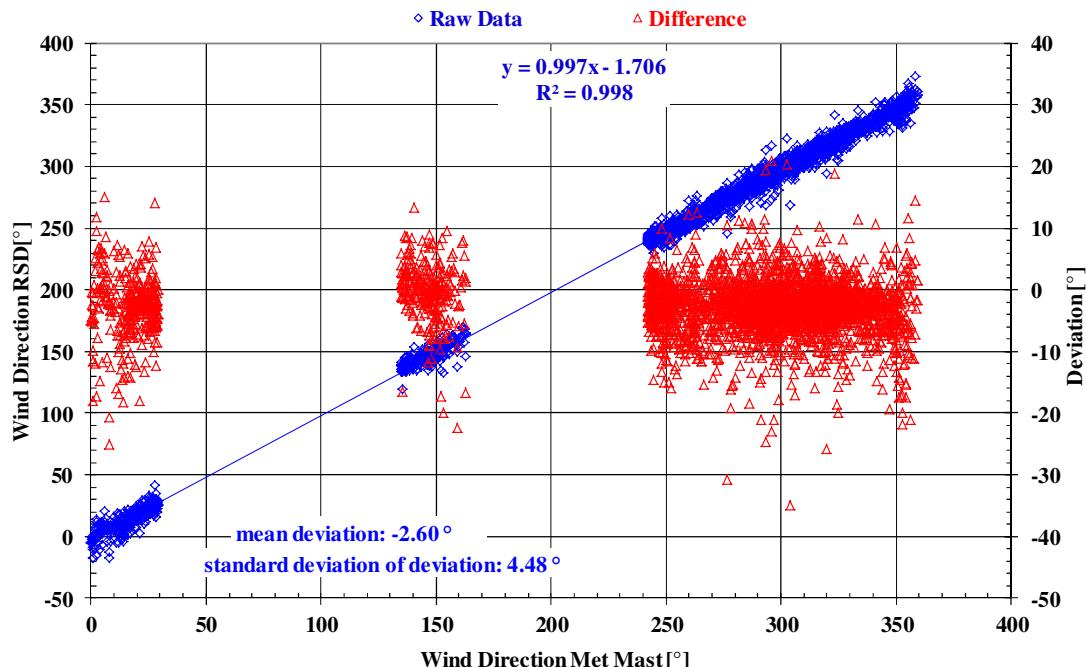

Figure 4.27: Scatter plot of wind direction as measured by RSD at 140 m height above ground against vane readings at 129 m measurement height.

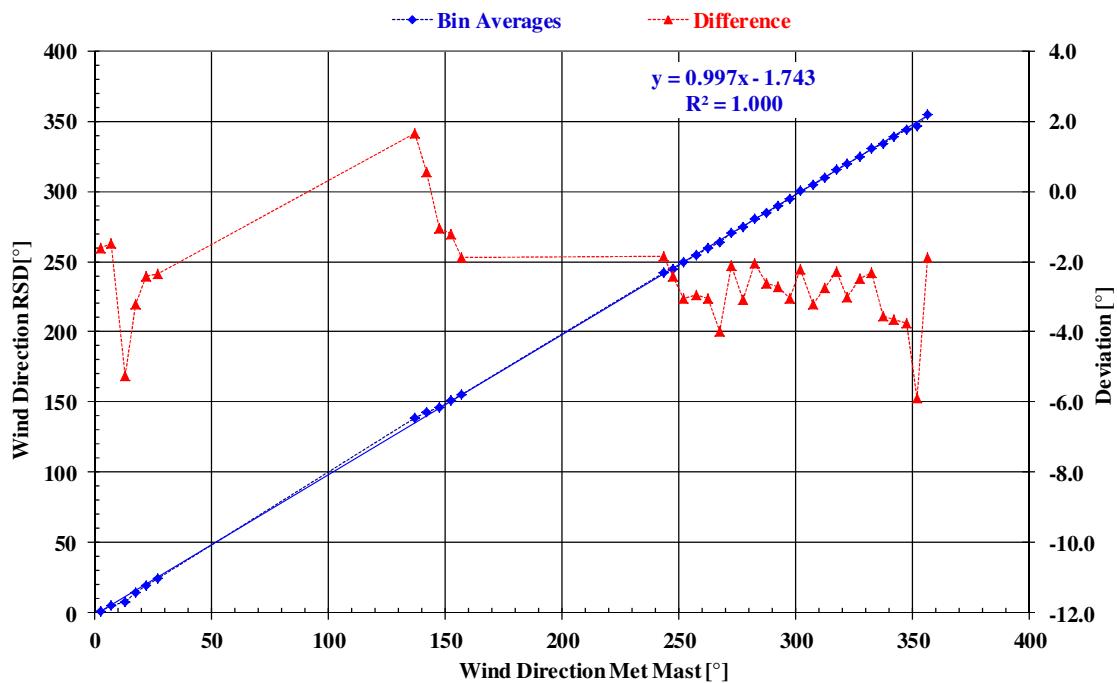

Figure 4.28: Bin analysis of wind direction as measured by RSD at 140 m height above ground against vane readings at 129 m measurement height.

Table 4.14 Bin analysis of wind direction as measured by RSD at 120 m height above ground against vane readings at 118.3 m measurement height. A positive sign of the shown deviation represents higher values measured by RSD. The right column shows the total expanded uncertainty (k=2) of the RSD as derived from the test.

#### 4.4.3 Wind Direction at 100 m Height

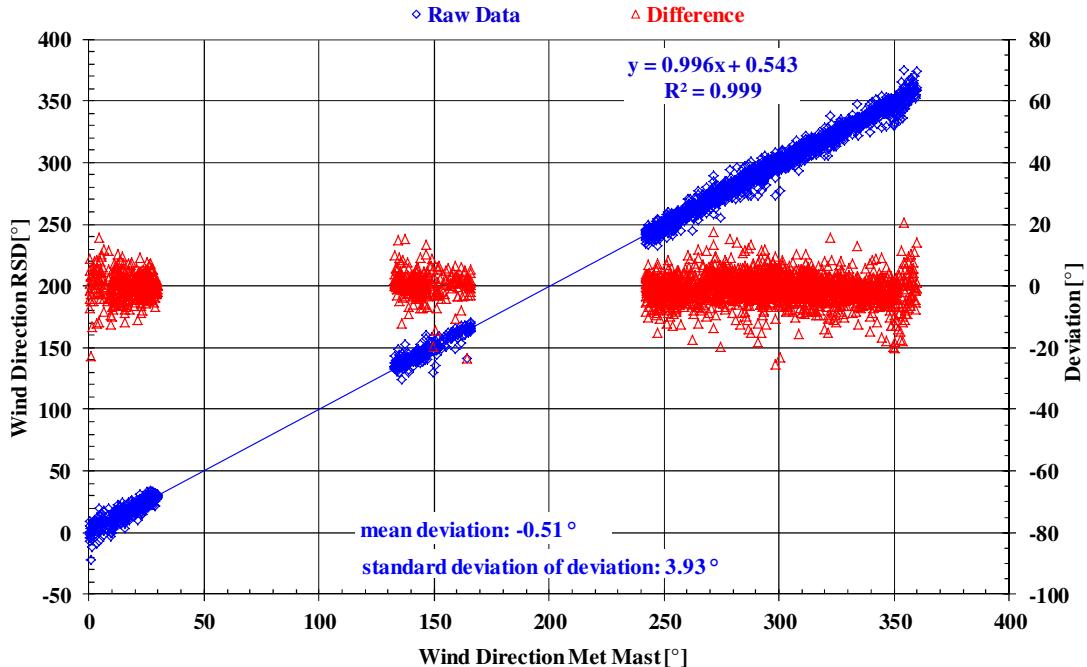

Figure 4.31: Scatter plot of wind direction as measured by RSD at 100 m height above ground against vane readings at 98.2 m measurement height.

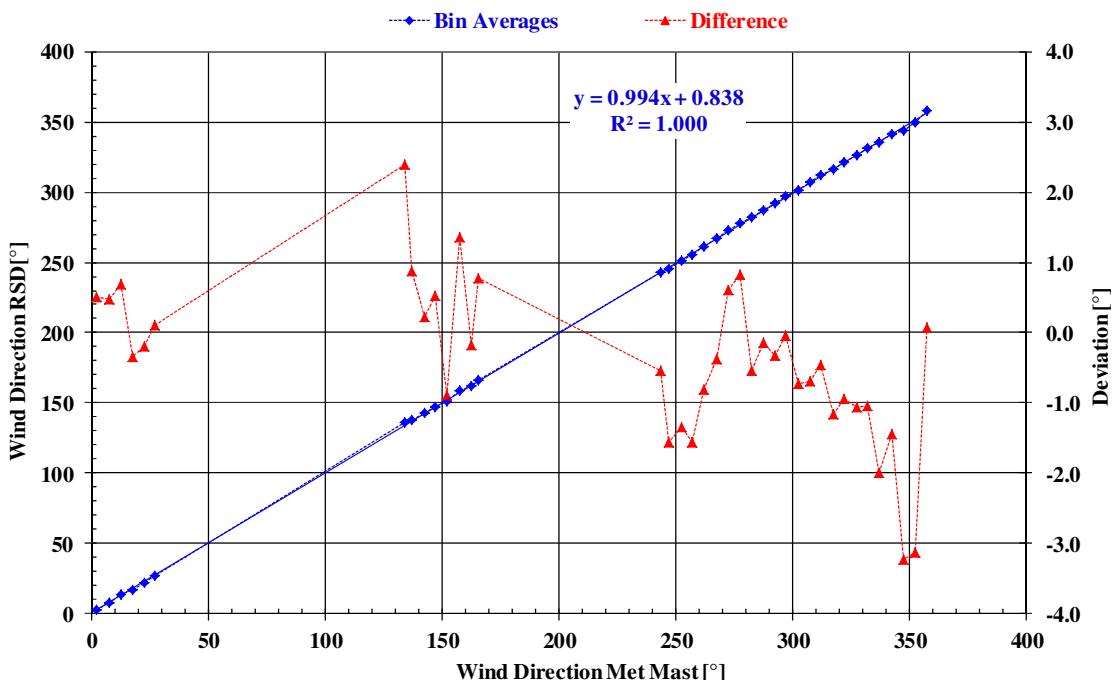

Figure 4.32: Bin analysis of wind direction as measured by RSD at 100 m height above ground against vane readings at 98.2 m measurement height.

Table 4.18 Bin analysis of wind direction as measured by RSD at 40 m height above ground against vane readings at 38.2 m measurement height. A positive sign of the shown deviation represents higher values measured by RSD. The right column shows the total expanded uncertainty (k=2) of the RSD as derived from the test.

#### 4.5 Correction of Horizontal Wind Speed

The evaluation of the tested RSD showed an overestimation of the horizontal wind speed larger than the reference uncertainty in all measurement heights. Therefore a correction function was calculated and applied to the measured data. The same correction function ( $y=0.977x + 0.034$ ) was applied to the 10-min average values of horizontal wind speed component in every height level of RSD between 60 m and 140 m.

The correction function was calculated by creating a linear regression of horizontal wind speed component measured by the reference anemometer as function of measurand by the RSD of each height. The results were averaged to  $y=0.977x + 0.034$ .

The calibration procedure as in chapter 4.2 is applied to the corrected data. The results are shown in the following figures and tables. The correction has the following effects on the results:

- The mean deviation is reduced to the range between -0.04 m/s and -0.01 m/s (-0.5 % to 0.0 %)
- Uncertainties ( $k=2$ ) in the range below 8 m/s were reduced by about 2 % to 3 % for measurement heights 140 m to 100 m and by 0 % to 2 % for the measurement heights of 60 m and 80 m. Above 8 m/s no systematic improvement or regression of uncertainties occurs, with changes varying between -2 % and 2 % of uncertainty ( $k=2$ ) between different wind speed bins.
- Correlation and scatter are not influenced by the correction.

It is noted that the uncertainty of the RSD as resulting from this comparison does not reflect all uncertainties of the system during an application at another site. The following additional uncertainties should be considered for an application of the system:

- The RSD measurements are influenced by environmental conditions, like e.g. wind shear. Thus, there is an additional uncertainty due to different environmental conditions during the calibration and during the application of the RSD.
- Mounting errors of the RSD during an application (vertical alignment)

Detailed ambient conditions dependent on wind speed and wind direction which were present during the test can be seen in Appendix A. These are the same as for the uncorrected data presented in chapter 4.2.

#### 4.5.1 Accuracy of RSD in Terms of 10-Minute Averages of the Horizontal Wind Speed Component at 140 m Measurement Height (correction applied)

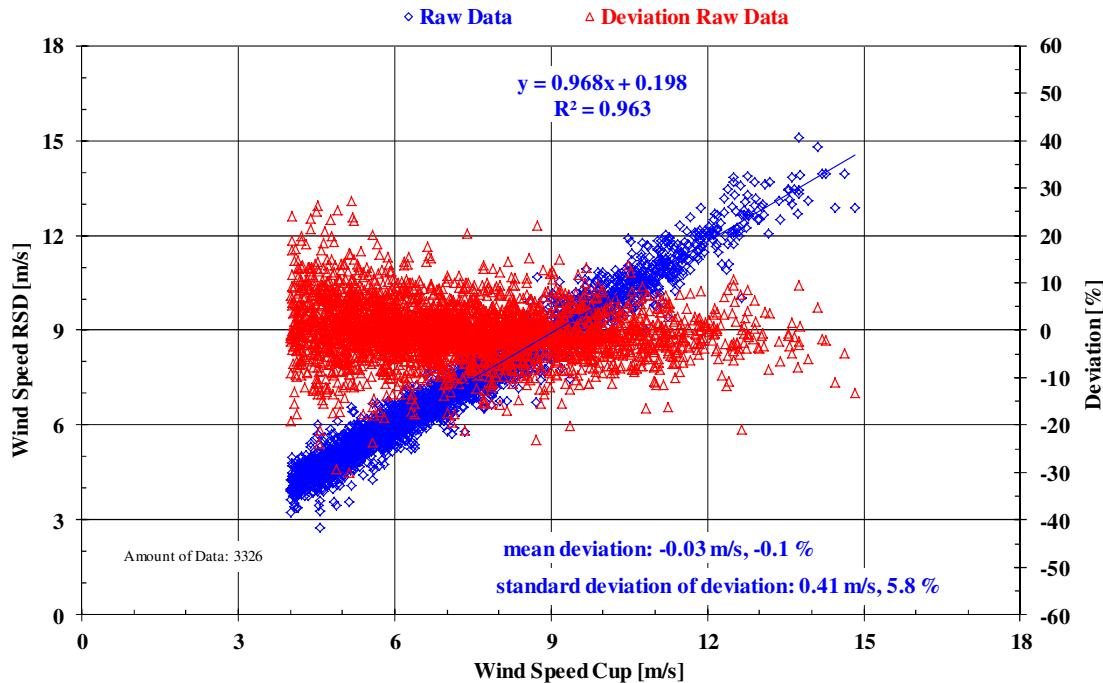

Figure 4.39 Scatter plot of horizontal wind speed component as measured by RSD against cup anemometer readings at 140 m height above ground and the deviation between both values in percent of the wind speed. Each point represents a 10-minute average. A correction offset of  $y = 0.977x + 0.034$  was applied to horizontal wind speed component of RSD.

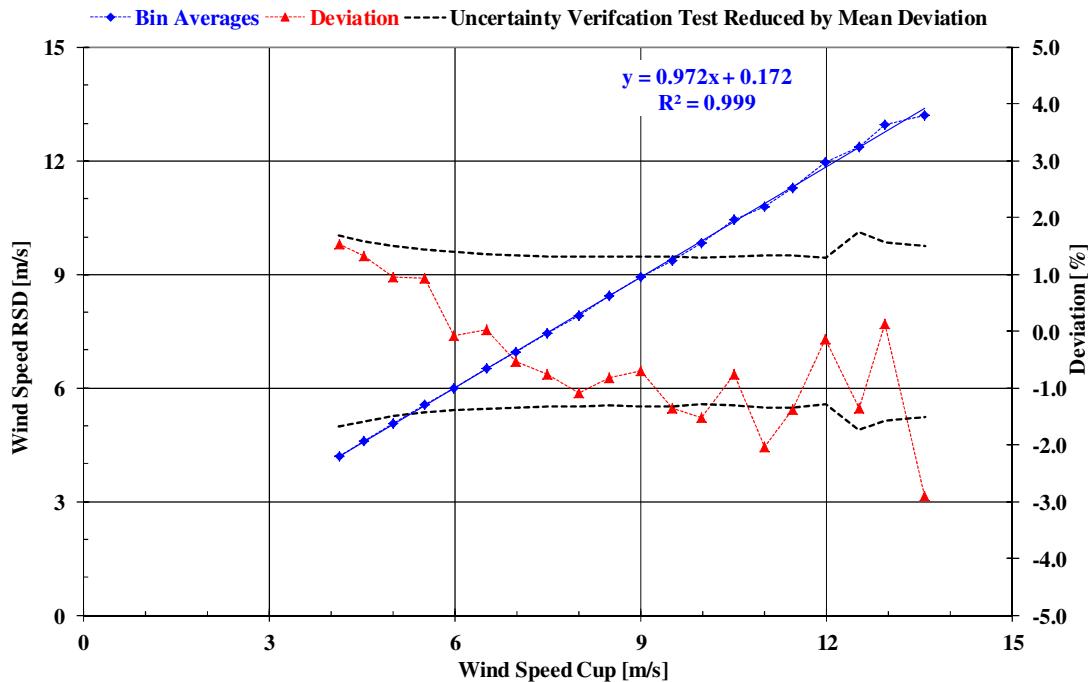

Figure 4.40: Bin analysis of 10-minute averages of the horizontal wind speed component measured by RSD against cup anemometer measurements at 140 m height above ground. A positive sign of the shown deviation represents higher values measured by RSD. A correction offset of  $y = 0.977x + 0.034$  was applied to horizontal wind speed component of RSD.

Table 4.23 Bin analysis of 10-minute averages of the horizontal wind speed component measured by RSD against cup anemometer measurements at 60 m height above ground. A positive sign of the shown deviation represents higher values measured by RSD. The right column shows the total expanded uncertainty (k=2) of the RSD as derived from the test. A correction offset of  $y = 0.977x + 0.034$  was applied to horizontal wind speed component of RSD.

## 4.6 Accuracy of the RSD in Terms of Sigma w

The standard deviation of the vertical wind speed component *sigma w* as measured by the RSD and by the ultra-sonic anemometers is compared for measurement heights of 130 m and 100 m in the following sub chapter. The following conclusions can be drawn:

- The RSD shows similar results for both evaluated measurement heights of 130 m and 100 m. For values of *sigma w* below 0.2 the deviation between RSD and reference shows significant high values.
- The squared correlation is between about 0.72 for measurement height of 130 m and 0.78 for measurement height of 100 m.

### 4.6.1 Accuracy of RSD in Terms of 10-Minute Averages of *sigma w* at 130 m Measurement Height

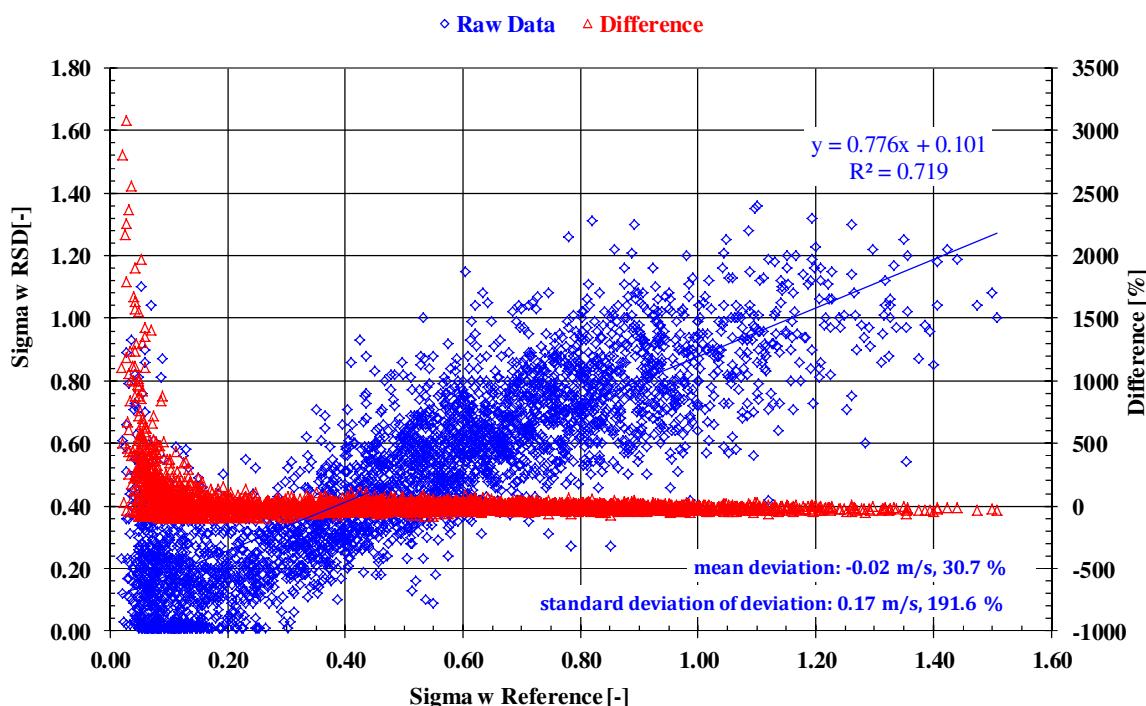

Figure 4.49 Scatter plot of standard deviation of vertical wind speed component (*sigma w*) as measured by RSD at 140 m against ultra-sonic anemometer readings at 130 m height above ground and the deviation between both values in percent of the wind speed. Each point represents a 10-minute average.

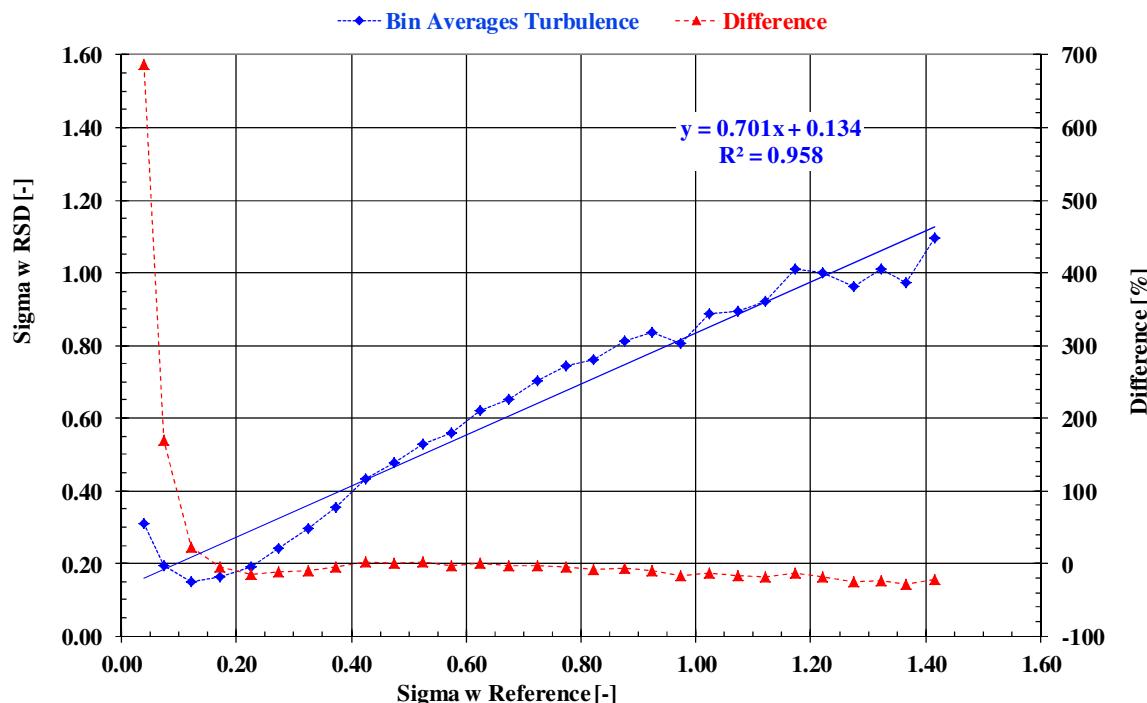

Figure 4.50: Bin analysis of 10-minute averages of standard deviation of vertical wind speed component (sigma w) measured by RSD in 140 m against ultra-sonic measurement at 130 m height above ground. A positive sign of the shown deviation represents higher values measured by RSD.

#### 4.6.2 Accuracy of RSD in Terms of 10-Minute Averages of sigma w at 100 m Measurement Height

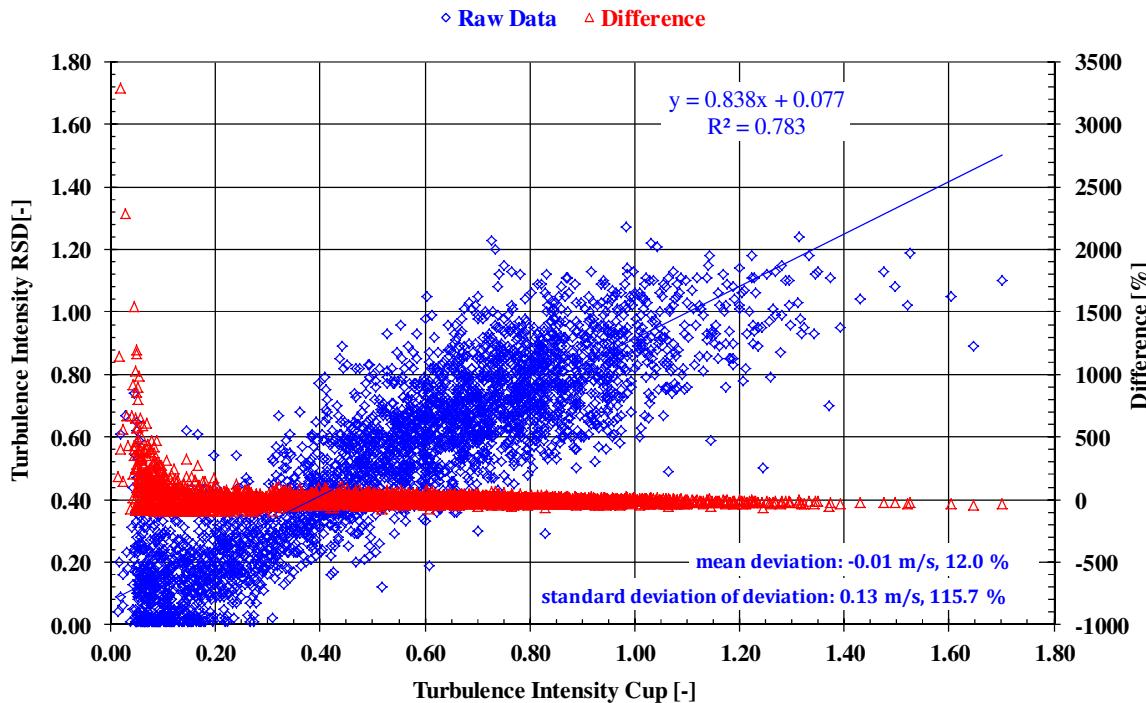

Figure 4.51 Scatter plot of standard deviation of vertical wind speed component (sigma w) as measured by RSD at 100 m against ultra-sonic anemometer readings at 100 m height above ground and the deviation between both values in percent of the wind speed. Each point represents a 10-minute average.

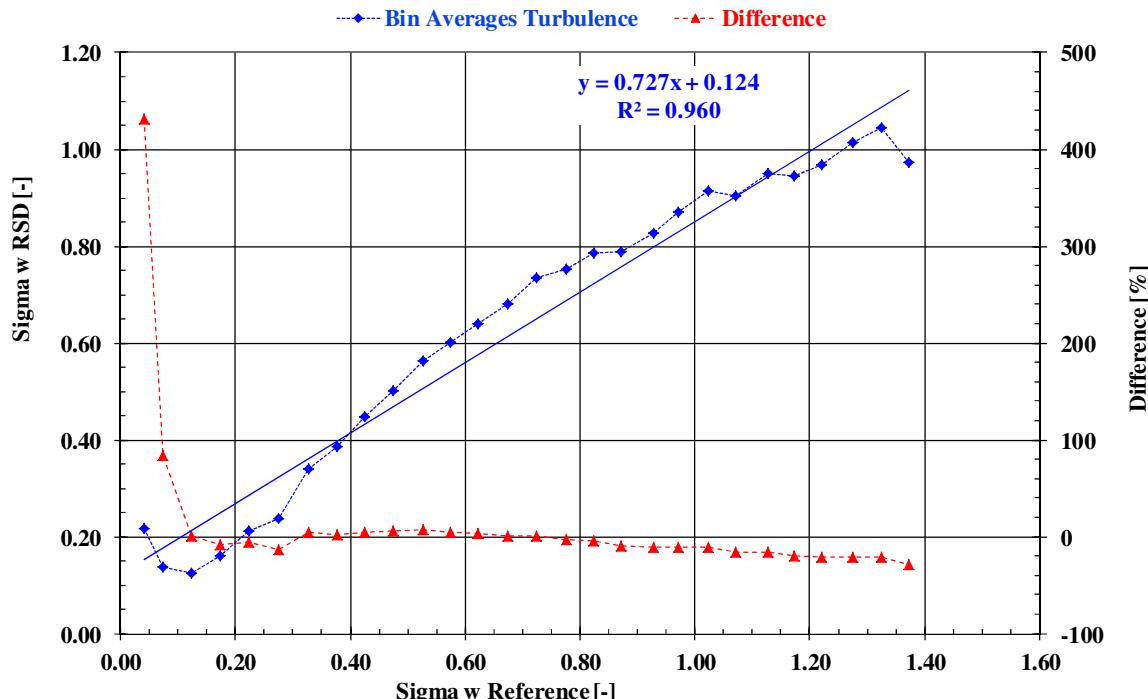

Figure 4.52: Bin analysis of 10-minute averages of standard deviation of vertical wind speed component (sigma w) measured by RSD in 100 m against ultra-sonic measurement at 100 m height above ground. A positive sign of the shown deviation represents higher values measured by RSD.

## 5 Conclusions

The accuracy of the sodar of type PA0, serial number 239, has been tested against cup anemometers mounted between 40 m and 135 m measurement height on a 135 m high met tower in flat terrain. The met mast is equipped with cup anemometers of high accuracy class and vanes at height levels of about 135 m, 131 m, 120 m, 100 m, 80 m 60 m 40 m and 20 m. All anemometers have been calibrated according to MEASNET by Deutsche WindGuard Wind Tunnel Services GmbH. The respective wind tunnel of Deutsche WindGuard is applied by the German Authority for the standardisation of units, Physikalisch-Technische Bundesanstalt (PTB), as German reference for the definition of the unit m/s in airflow measurements. A more accurate reference for cup anemometers is not available. The anemometers on the mast are mounted according to IEC 61400-12-1 [1] and the extended requirements of the draft revision of IEC 61400-12-1 [2]. Mast influences at the lower measurement heights like blockage and flow acceleration effects have been corrected empirically. Wind directions with the sensors of the mast or with the RSD in wakes of the mast or of neighbouring wind turbines have been excluded from the test. There has been no preliminary intercomparison period before the official start of the calibration period.

The data evaluation covers a calibration, which describes the accuracy of the tested sodar unit under the conditions during the test.

The main results of the calibration are:

- Depending on measurement height, the database consists of 2688 to 3348 10-minute datasets (1080 are required). However only wind speed bins up to 14.4 m/s are completed (up to 16 m/s is required). Therefore, the database available for the verification test at hand does not fulfil the completeness criteria of the draft IEC 61400-12-1, ed. 2. This deviation is not serious as completed test allows a good estimation of the instruments performance.
- The RSD shows a good correlation to cup anemometer measurements in terms of 10-minute averages of the horizontal wind speed component. At heights 140 m to 80 m measurement height the square of correlation coefficient is 0.95 to 0.96. At lower heights of 60 m and 40 m the correlation decreases to 0.94 and 0.89, respectively.
- The instrument overestimates slightly, with mean deviation of the measurements of the horizontal wind speed component measured by the tested RSD and by the reference cup anemometers is with 1.7 % or 0.1 m/s.
- The overestimation is more significant with wind speeds lower than 7 m/s and decreases within the uncertainty of the reference measurement uncertainty.
- The resulting wind speed dependent uncertainties of the measurements of the horizontal wind speed component by the RSD are in the order of about 3-6% (expanded uncertainty  $k=2$ ) in most wind speed bins for all measurement heights. The variation of the uncertainty reaches from 2.7% to 18% for the different measurement heights and wind speed bins
- A correction with a height independent function  $y=0.977 \cdot x + 0.034$  m/s reduces the mean deviation to less than 0.5 m/s. Uncertainties ( $k=2$ ) in the range below 8 m/s were reduced by about 2 % to 3 % for measurement heights 140 m to 100 m and by 0 % to 2 % for the measurement heights of 60 m and 80 m. Above 8 m/s no systematic improvement or regression of uncertainties occurs, with changes varying between -2 % and 2 % of uncertainty ( $k=2$ ) between different wind speed bins.

- The wind direction as measured by the RSD correlates good to the wind direction as measured by vane on the met mast (squared correlation coefficient above 0.998).
- The RSD shows a data availability of about 80 % up to 100 m. Above 100 m the availability decreases to 62 % at 200 m. Especially during too heavy rain the instrument discards measurement values.
- Erroneous data occurred by heavy rain are recognized by the RSD itself reliable so a post filtering was not necessary.

It is pointed out that all shown uncertainties of the measurement of the RSD represent two standard uncertainties (expanded uncertainty  $k=2$ ) as it is required according to DWG's accreditation for calibrations of RSD's. In contrast to that, it is common practice to apply only the single standard uncertainty of wind measurements for most applications throughout the wind energy industry as for instance in case of wind resource assessments or wind turbine power curve tests. The expanded uncertainty ( $k=2$ ) with the confidence of 95% has the twice uncertainty. To get the single uncertainty ( $k=1$ ) with confidence of 68%, the expanded uncertainty has to be divided by two.

Table 8.12 Average and standard deviation of measured ambient conditions in 40 m during test

### 8.3 Accuracy in Terms of the Horizontal Wind Speed Component without wind speed limitation

This chapter represents the results of the comparison of cup anemometer measurement and measurement of the RSD in terms of the horizontal wind speed component. It is similar to chapter 4.2 with the difference that no wind speed filter has been applied.

#### 8.3.1 Accuracy of RSD in Terms of 10-Minute Averages of the Horizontal Wind Speed Component at 140 m Measurement Height

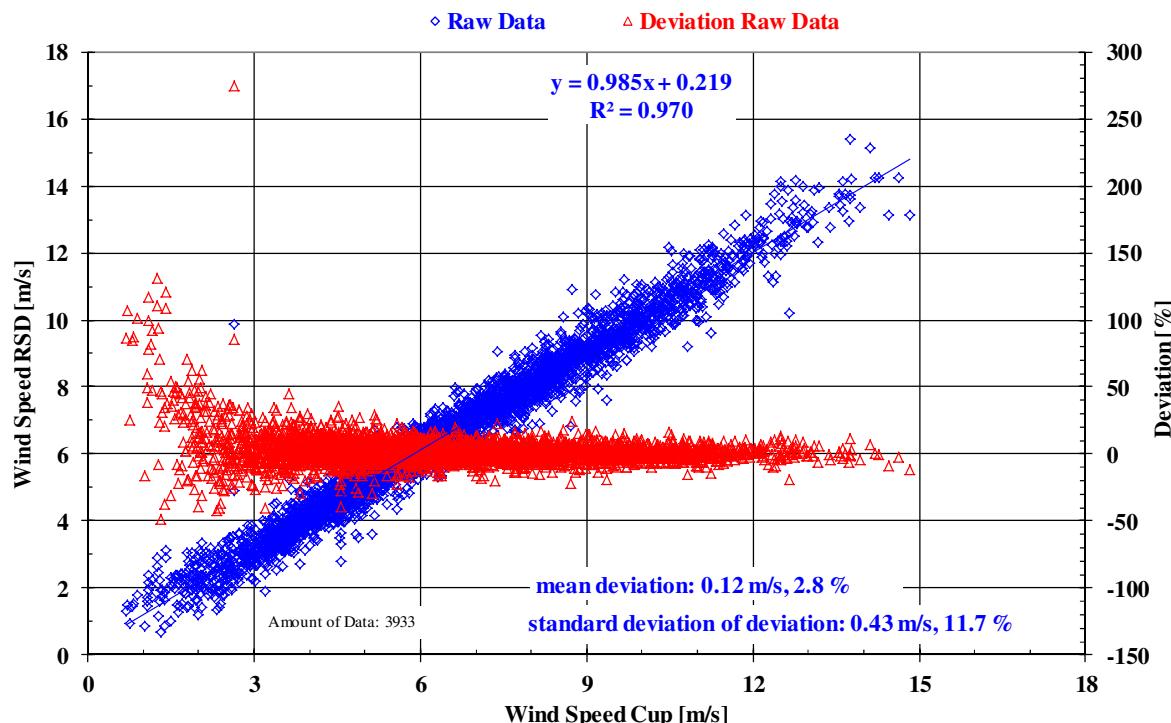

Figure 8.1 Scatter plot of horizontal wind speed component as measured by RSD against cup anemometer readings at 140 m height above ground and the deviation between both values in percent of the wind speed. Each point represents a 10-minute average.

### 8.3.2 Accuracy of RSD in Terms of 10-Minute Averages of the Horizontal Wind Speed Component at 120 m Measurement Height

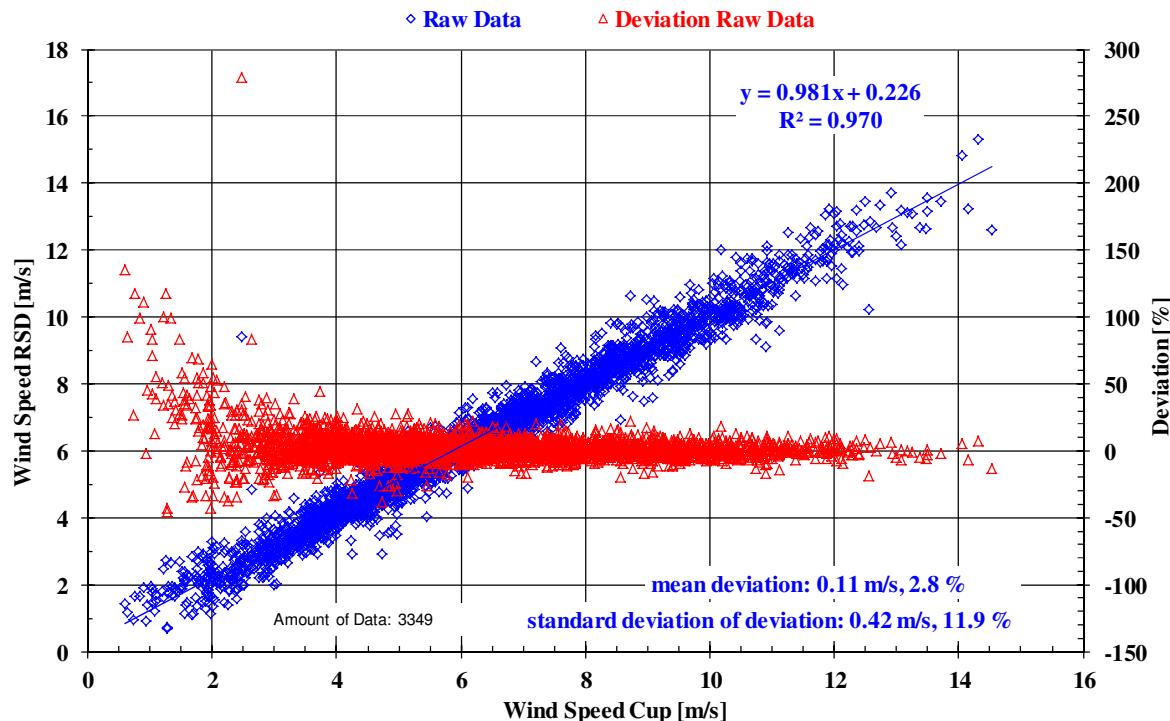

Figure 8.2 Scatter plot of horizontal wind speed component as measured by RSD against cup anemometer readings at 120 m height above ground and the deviation between both values in percent of the wind speed. Each point represents a 10-minute average.

### 8.3.3 Accuracy of RSD in Terms of 10-Minute Averages of the Horizontal Wind Speed Component at 100 m Measurement Height

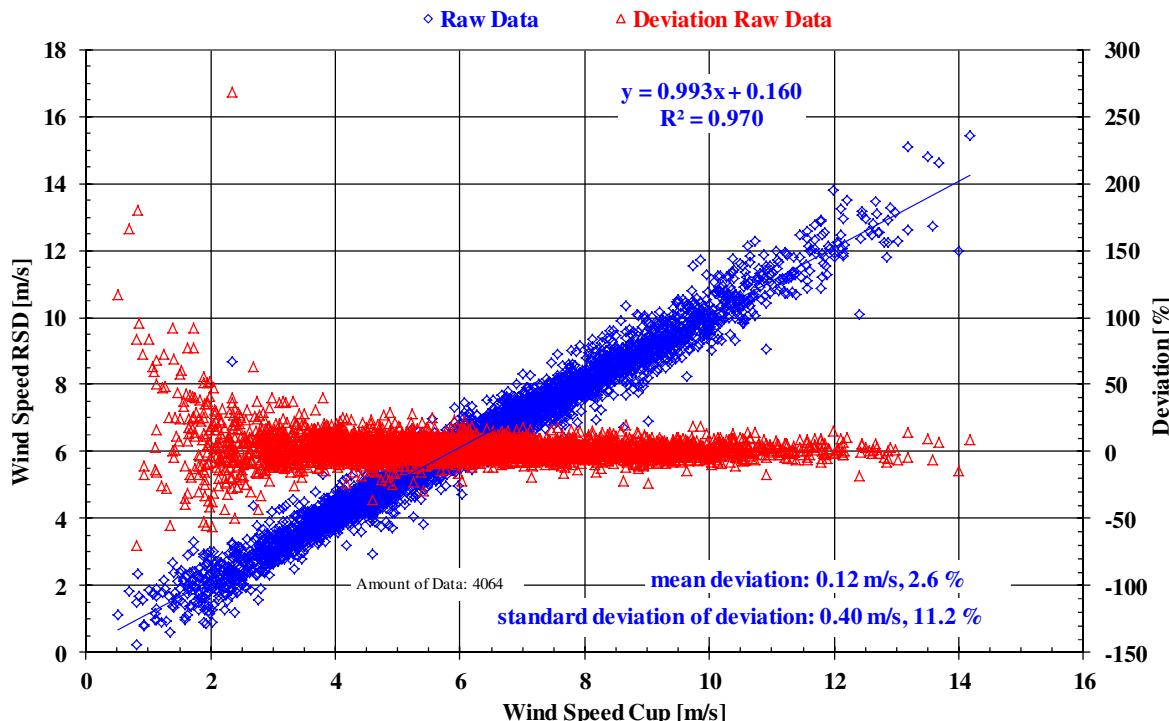

Figure 8.3 Scatter plot of horizontal wind speed component as measured by RSD against cup anemometer readings at 100 m height above ground and the deviation between both values in percent of the wind speed. Each point represents a 10-minute average.

### 8.3.4 Accuracy of RSD in Terms of 10-Minute Averages of the Horizontal Wind Speed Component at 80 m Measurement Height

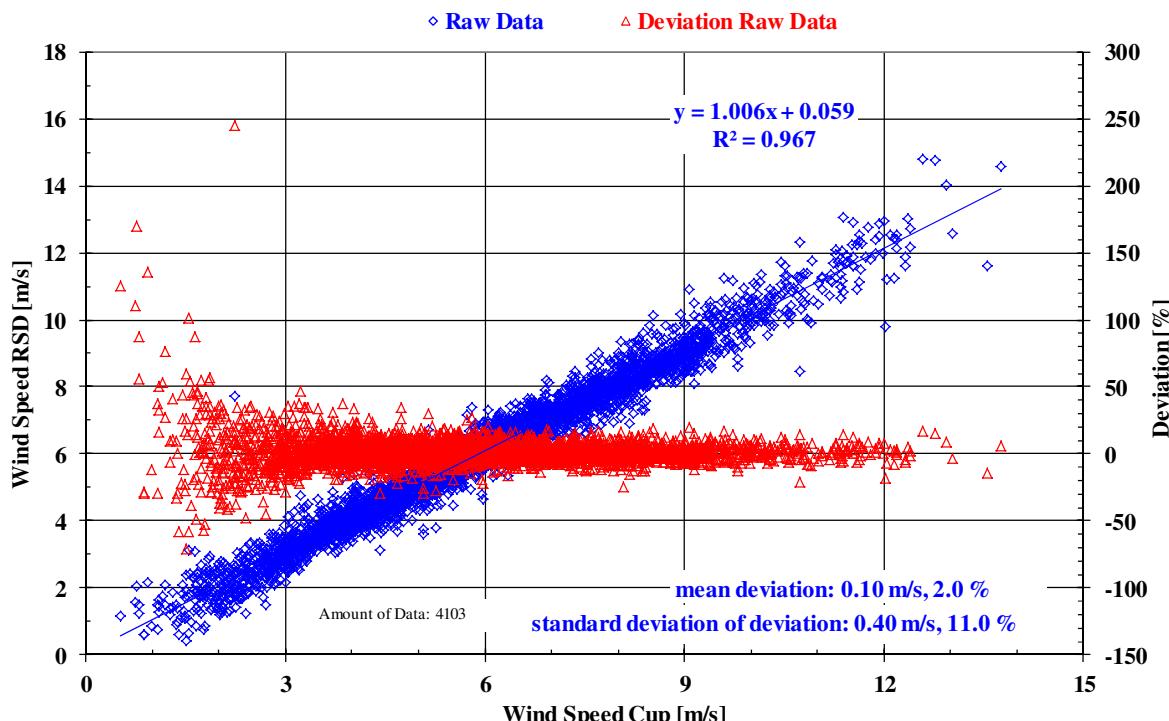

Figure 8.4 Scatter plot of horizontal wind speed component as measured by RSD against cup anemometer

readings at 80 m height above ground and the deviation between both values in percent of the wind speed. Each point represents a 10-minute average.

### 8.3.5 Accuracy of RSD in Terms of 10-Minute Averages of the Horizontal Wind Speed Component at 60 m Measurement Height

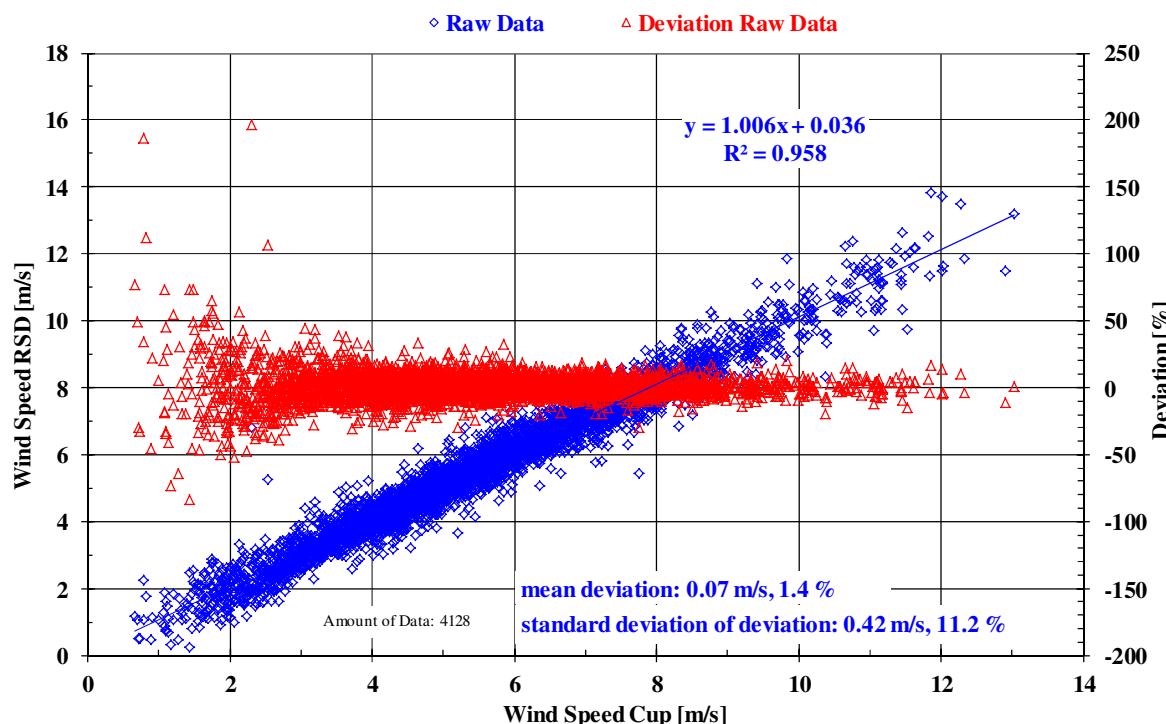

Figure 8.5 Scatter plot of horizontal wind speed component as measured by RSD against cup anemometer readings at 60 m height above ground and the deviation between both values in percent of the wind speed. Each point represents a 10-minute average.

### 8.3.6 Accuracy of RSD in Terms of 10-Minute Averages of the Horizontal Wind Speed Component at 40 m Measurement Height

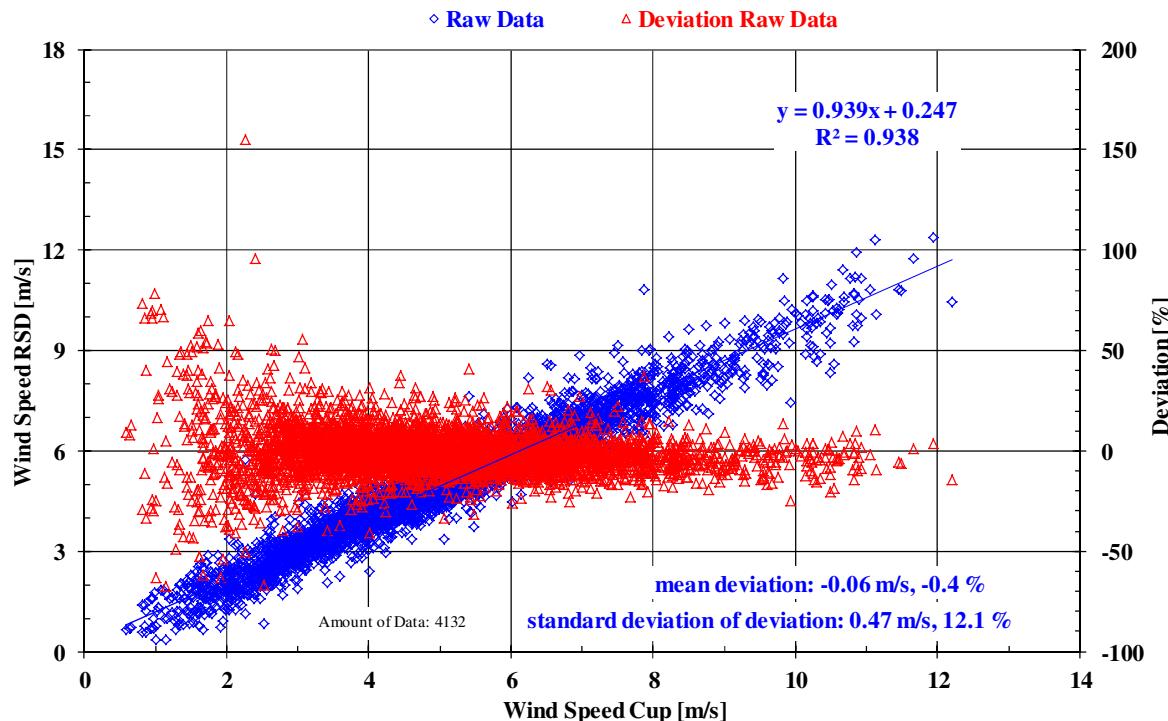

Figure 8.6 Scatter plot of horizontal wind speed component as measured by RSD against cup anemometer readings at 40 m height above ground and the deviation between both values in percent of the wind speed. Each point represents a 10-minute average.
